

Sérgio Sousa (IA)
ExoEarths Team (http://www.astro.up.pt/exoearths/)

#### **Advance Course Outline:**

- Lesson 1: Python basics (T + P)
- Lesson 2: Python with Numpy and Matplotlib (T + P)
- Lesson 3: Science and Astronomy modules (Scipy, Pyfits, Pyraf) (T + P)

Lesson 2: Python with Numpy and Matplotlib

- Object Oriented (OO) Definition of objects/classes
- Numpy: creating and manipulation numerical data
- Plotting with Matplotlib

### Object Oriented Paradigm

#### Why shall we care about Object Oriented programing???

- Objects are a metaphor that permits a good division of the code and abstraction of the reality
- Allow an easy way to implement changes to existing code or to add new code without changing/destroying much of what was done before.
- Python is based on OO and so are most of the libraries available.
- Almost everything in Python is an object (even functions are in fact Python objects)

#### Defining Objects/Classes

#### Simple approach

Class Variables

Instance Variables

Instance Methods (self)

Class Methods (static)

#### Running this code:

```
Hello
1.1
0.98
7.64392336526e-11
['O', 'B', 'A', 'F', 'G', 'K', 'M']
```

```
class Star:
  """ A simple Star class"""
  grav = 6.67384e-11 # Gravitional constant
  def __init__(self, massin,radiusin):
    self.mass = massin
    self.radius = radiusin
  def get surface gravity(self):
    return Star.grav*self.mass/self.radius**2
  @staticmethod
  def get_spectral_types():
    return ['0','B','A','F','G','K','M']
## My functions:
### Main program:
def main():
  print "Hello"
  s1=Star(1.1,0.98)
  print s1.mass
  print s1.radius
  print s1.get surface gravity()
  print Star.get spectral types()
```

# 00 things to explore

#### Object built-in functions and Operators Overloading

```
1. __init__ ( self [,args...] )
```

Constructor (with any optional arguments)
Sample Call : obj = className(args)

2. \_\_del\_\_( self )

Destructor, deletes an object. Sample Call : dell obj

3. \_\_repr\_\_( self )

Evaluatable string representation. Sample Call: repr(obj)

4. \_\_str\_\_( self )

Printable string representation. Sample Call: str(obj)

5. \_\_cmp\_\_ ( self, x )

Object comparison. Sample Call: cmp(obj, x)

6. \_\_add\_\_(self, other)

Adding objects: Overloading of + operator. Sample Call: obj1 + ob2

```
🙉 🖨  ObjectOverloading (~/Dropbox/Python/AdvancedCourse/examples) - gedit
    🛁 Open 🔻 🛂 Save 🛮 💾 🕽 🤚 Undo 🧀
ObjectOverloading ×
1 #!/usr/bin/python
 class Vector:
    def init (self, a, b):
       self.a = a
       self.b = b
    def __str__(self):
       return 'Vector (%d, %d)' % (self.a, self.b)
    def add (self,other):
       return Vector(self.a + other.a, self.b + other.b)
 v1 = Vector(2.10)
 v2 = Vector(5, -2)
6 print v1 + v2
                             Python *
                                        Tab Width: 24 ▼
                                                           Ln 16, Col 14
                                                                          INS
```

\$ ./ObjectOverloading.py
Vector (7, 8)

#### 00 things to explore

#### OO Keywords to read about:

- **Abstraction:** The extraction of the key carachteristics of a concept or entity from the real world to allow their representation in a computer.
- Encapsulation: The values of the variables inside an object are private, unless methods are written to pass that information outside of the object. (Not practicable in Python)
- Inherance: Each subclass inherits all variables and methods of its superclass. (e.g. Animal is a superclass of Dog and Cat
- Polymorphism: Each object can behave as a super class object (e.g. Cat and Dog can behave as Animal)

Other interesting OO keywords to explore for complex applications:

- Abstract Classes
- Interfaces

#### Good Practices in Python

- Explicit variable names (no need of a comment to explain what is in the variable)
- Style: spaces after commas, around =, etc. A certain number of rules for writing "beautiful" code (and, more importantly, using the same conventions as everybody else!) are given in the Style Guide for Python Code and the Docstring Conventions page (to manage help strings).
- Except some rare cases, variable names and comments in English.
- Good identation (forced in Python)

Lesson 2: Python with Numpy and Matplotlib

- Object Oriented (OO) Definition of objects/classes
- Numpy: creating and manipulation numerical data
- Plotting with Matplotlib

#### Numpy

```
>>> import numpy
>>> help(numpy)
```

```
Sousasag@asusg51jx: ~/posdoc/docs/isep/AULAS/PPROG
Help on package numpy:

NAME
    numpy

FILE
    /usr/lib/python2.7/dist-packages/numpy/__init__.py

DESCRIPTION
    NumPy
    =====
```

#### Provides

- 1. An array object of arbitrary homogeneous items
- 2. Fast mathematical operations over arrays
- 3. Linear Algebra, Fourier Transforms, Random Number Generation

#### Numpy Array vs. Python list

```
example timeit numpy.pv x
1 #!/usr/bin/python
2 ## My first python code
4 ##imports:
5 import numpy as np
6 import timeit
8 ## My functions:
10 def normal list():
  L = range(1000000)
   L2 = [i**2 for i in L]
15 def numpy_array():
   a = np.arange(1000000)
   a2 = a**2
19 ### Main program:
20 def main():
   print "Normal List:"
   timer = timeit.Timer("normal list()", setup="from __main__ import normal list")
   print timer.timeit(1)*1000. , 'mili seconds'
   print "Numpy Array:"
   timer = timeit.Timer("numpy_array()", setup="from __main__ import numpy_array")
   print timer.timeit(1)*1000. , 'mili seconds'
main()
```

```
$ ./example_timeit_numpy.py
Normal List:
140.730142593 mili seconds
Numpy Array:
7.87591934204 mili seconds
```

• Create Arrays: direct definition

```
>>> import numpy as np
>>> a = np.array([0,1,2,3]) # 1D array
>>> b = np.array([[0, 1, 2], [3, 4, 5]]) # 2D array: 2 x 3 array
>>> c = np.array([[[1], [2]], [[3], [4]]]) # 3D Array
>>> # evenly spaced:
                                                   Same as range in built in Python
>>> d = np.arange(10)
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> e = np.arange(1,9,2) # start, end (exlusive), step
array([1, 3, 5, 7])
>>> # by a number of points
>>> f = np.linspace(0, 1, 6) # start, end, num-points 🛶
                                                                    Defining a linear space array
array([0., 0.2, 0.4, 0.6, 0.8, 1.])
>>> a
array([0, 1, 2, 3])
>>> a.ndim
>>> b
array([[0, 1, 2],
      [3, 4, 5]])
                                   Some properties of the array object
>>> b.ndim
>>> len(a)
>>> b.shape
             This is a tuple
(2, 3)
```

• Create Arrays: automatic definitions

```
>>> # creation of predefined arrays:
>>> a = np.ones((3, 3))
>>> # reminder: (3, 3) is a tuple
array([[1., 1., 1.],
      [ 1., 1., 1.],
      [1., 1., 1.]
                                       ones and zeros also work for 1D
>>> b = np.zeros((2,2))
>>> b
array([[ 0., 0.],
      [ 0., 0.]])
>>> c = np.eye(3)
>>> C
array([[ 1., 0., 0.],
      [ 0., 1., 0.],
                                           Defining an Identity matrix
       [0., 0., 1.]])
>>> d = np.diag([1,2,3,4])
>>> d
array([[1, 0, 0, 0],
      [0, 2, 0, 0],
                                             Defining a diagonal matrix
      [0, 0, 3, 0],
       [0, 0, 0, 4]])
```

• Create Arrays: setting different data types

```
>>> #creating with different data types
>>> a = np.array([1, 2, 3])
>>> a.dtype
dtype('int64')
                                               automatic definition
>>>
>>> a = np.array([1., 2., 3.])
>>> a.dtype
dtype('float64')
>>>
>>> a = np.array([1, 2, 3], dtype=float) #bool, complex
>>> a.dtype
dtype('float64')
                                                                  Forcing the types
>>> a = np.array([1, 2, 3], dtype=complex) #bool, complex
>>> a.dtype
dtype('complex128')
```

• Indexing in Arrays – getting the values that you need

```
>>> #indexing and Slicing
>>> a = np.arange(10)
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
                                               Indexing arrays is the same as for lists
>>> a[0], a[2], a[-1]
(0, 2, 9)
>>> #index in numpy 2D: 2ways:
\dots a = np.diag(np.arange(3))
>>> a
array([[0, 0, 0],
      [0, 1, 0],
>>> a[1][1]
             #using a tuple
>>> a[1,1]
                                        You can also use tuples for arrays,
>>> a[(1,1)]
                                        simpler notation for n>1 Dimensional arrays
>>> a[1,2] = 26
>>> a
array([[ 0, 0, 0],
       [0, 1, 26],
>>> a[1]# geting a line
                                          Getting lines and/or rows from a matrix
array([ 0, 1, 26])
>>> a[:,2]# getting a row
```

array([ 0, 26, 2])

Create Arrays: Slicing and Views

```
>>> #slicing:
... a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> a[2:9:3] # start;end;step
array([2, 5, 8])
>>> a[:4]
array([0, 1, 2, 3])
>>> a[2:]
array([2, 3, 4, 5, 6, 7, 8, 9])
>>> a[::2]
array([0, 2, 4, 6, 8])
```

Sintaxe for slicing: array[start:end:step]

Some useful variations

```
>>> #slicing create views, using the same memory... Careful
...
>>> a = np.arange(10)
>>> a
array([0, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> b = a[::2]
>>> b
array([0, 2, 4, 6, 8])
>>> b[0] = 26
>>> b
array([26, 2, 4, 6, 8])
>>> a
array([26, 1, 2, 3, 4, 5, 6, 7, 8, 9])
>>> # to copy use:
... b = a[::2].copy() # this force a copy
>>> b[0] = 12
>>> b
array([12, 2, 4, 6, 8])
```

array([26, 1, 2, 3, 4, 5, 6, 7, 8, 9])

>>> a

#### Important to be aware:

Slicing create views that share the same memory of the original array;

If you want to copy you need to force the copy;

Create Arrays: Applying masks (can be used as where in IDL)

```
Next slide for random
>>> #masks (similar to where in IDL)
                                                                      numbers (wait for it...)
>>> a = np.random.random integers(0, 20, 15)
array([ 6, 18, 6, 3, 5, 14, 15, 16, 8, 1, 20, 20, 5, 7, 8])
                                                                         Defining a mask
>>> mask = (a % 2 == 0)
>>> mask
                                                                         (which will be an array
array([ True, True, True, False, False, True, False, True, 🕶
                                                                         of booleans)
      False, True, True, False, False, True], dtype=bool)
>>> even a = a[mask] # this create a copy, not a view
>>> even a
                                                                         Applying the mask
array([ 6, 18, 6, 14, 16, 8, 20, 20, 8])
>>>
>>> # useful for taging
... a[a % 2 == 0] = -1
                                                                           Nice for tagging
>>> a
                                                                           (check example)
array([-1, -1, -1, 3, 5, -1, 15, -1, -1, 1, -1, -1, 5, 7, -1])
>>>
>>> a[[0,1,3]] = 26 # use a list to change n values in one line
>>> a
                                                                        Can also be used to
array([26, 26, -1, 26, 5, -1, 15, -1, -1, 1, -1, -1, 5, 7, -1])
                                                                        assign a value to
```

different places at once

• Create Arrays: Applying masks (can be used as where in IDL)

Using np.where()

Define some array with numbers

```
>>> import numpy as np
>>> x = np.arange(15)+12
>>> X
array([12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26])
>>> ix = np.where(x % 2 == 0)
>>> ix
(array([ 0, 2, 4, 6, 8, 10, 12, 14]),)
>>> x2 = x[ix]
>>> x2
array([12, 14, 16, 18, 20, 22, 24, 26])
>>> np.where(x % 2 == 0, x, -1)
array([12, -1, 14, -1, 16, -1, 18, -1, 20, -1, 22, -1, 24, -1, 26])
>>> X
array([12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26])
>>> x = np.where(x % 2 == 0, x, -1)
>>> X
array([12, -1, 14, -1, 16, -1, 18, -1, 20, -1, 22, -1, 24, -1, 26])
>>>
```

Using where. Similar as a mask

You can also tag with where

Can also be used to assign a value to different places at once

Create Arrays: Random numbers generation

```
>>> # creation of random numbers:
                                                             The standard random
>>> a = np.random.rand(4) # uniform in [0, 1]
                                                             common to many languages
A gaussian random number
                                                             generation. G(0,1)
>>> b = np.random.randn(4) # Gaussian
array([-1.07921219, -0.62811542, 0.29934704, 0.12727723])
                                                           Important: Careful with the seed to
>>> np.random.seed(1234) # Setting the random seed
                                                           generate the random numbers
>>> c = np.random.random integers(1,50,5) # 5 random integers
                                                            To generate the next
>>> C
                                                             Euromillions numbers
array([48, 20, 39, 13, 25])
>>>
>>> s = np.random.poisson(5, 10) # see help(np.random) for more distributions
>>> 5
array([5, 1, 4, 2, 6, 6, 6, 10, 2, 3])
```

You can also obtain random numbers following many other statistical distributions. ex. poisson

Create Arrays: Random numbers generation – The statistical distributions available

```

```

Arrays: Numerical Operations

```
>>> a = np.array([1,2,3,4])
>>> a + 1
array([2, 3, 4, 5])
>>> 2**a
array([2, 4, 8, 16])
>>> # arrays are objects, operators were overloaded
... b = np.ones(4) + 1
array([ 2., 2., 2., 2.])
>>> a - b
array([-1., 0., 1., 2.])
>>> a * b
array([2., 4., 6., 8.])
>>> # warning: NOT matrix multiplication
>>> c = np.ones((3,3))
>>> C
array([[ 1., 1., 1.],
      [ 1., 1., 1.],
      [1., 1., 1.]
>>> c * c
array([[ 1., 1., 1.],
      [ 1., 1., 1.],
      [ 1., 1., 1.]])
>>> # to multiply matrices:
>>> c.dot(c)
array([[ 3., 3., 3.],
      [ 3., 3., 3.],
      [ 3., 3., 3.]])
```

Numpy arrays are objects.

Most of the operators where overloaded to represent what we would like.

(One of the advantages of OO programing)

We can do straightforward operations with arrays (similar to IDL)

Careful with the multiplication of arrays:

Use array.dot(array) to do a proper algebra multiplication of arrays

Create Arrays: comparisons and reductions

```
>>> # comparisons
...
>>> a = np.array([1, 2, 3, 4])
>>> b = np.array([4, 2, 2, 4])
>>> a == b
array([False, True, False, True], dtype=bool)
>>> a > b
array([False, False, True, False], dtype=bool)
>>> #logical operations
... np.all([True, True, False])
False
>>> np.any([True, True, False])
True
```

There are several reductions that you can do directly from the arrays.

- sum all elements;
- get the mean;
- standard deviation;
- median (is a class method);
- get extremes in array;
- get index of extremes;

Another useful method is the sort(). The default algorithm is the quicksort, but you can choose others. (check with >>>help(np.sort))

The comparisons operatores are also overloaded. You can use it to compare directly arrays.

In addition you also have some useful logical operations in array

```
>>> # some basic reductions:
  >>> x = np.array([3, 10, 5, 1, 2, 7, 4])
  >>> np.sum(x)
  32
 >>> x.sum()
>>> x.mean()
  4.5714285714285712
>>> x.std()
  2.8713930346059686
 >>> np.median(x) # there is no x.median()...
  4.0
>>> x.min()
>>> x.max()
 >>> x.argmin() # index of minimum
  >>> x.argmax() # index of maximum
  >>> x.sort()
  array([ 1, 2, 3, 4, 5, 7, 10])
```

Create Arrays: reductions in 2D

```
>>> #notes on 2D or higher
>>> x = np.array([[1, 1], [2, 2]])
>>> X
array([[1, 1],
       [2, 2]])
>>>
>>> x.sum()
>>> x.sum(axis=0)
array([3, 3])
>>> x.sum(axis=1)
array([2, 4])
>>> x[:, 0].sum()
>>> x.T # transpose <
array([[1, 2],
       [1, 2]])
```

When you have 2D arrays (or with more dimensions) you can also use the methods.

You can also select the axis that you want to reduce using the option inside the method.

Or alternatively you use what you learn on the indexing/slicing

Special note:

How to quickly transpose a matrix

Create Arrays: data types casting and rounding

```
>>> # data types and Casting
... np.array([1, 2, 3]) + 1.5 # bigger type win
array([2.5, 3.5, 4.5])
>>>
>>> # assignment don't change type
... a = np.array([1, 2, 3])
>>> a.dtvpe
dtype('int64')
>>> a[0] = 1.9 \# float will be truncated <math>\neg
>>> a
array([1, 2, 3])
>>>
>>> #forced cast:
... a = np.array([1.7, 1.2, 1.6])
>>> b = a.astype(int) # <-- truncates to integer -
>>> b
array([1, 1, 1])
>>> # Rounding
>>> a = np.array([1.2, 1.5, 1.6, 2.5, 3.5, 4.5])
>>> b = np.around(a)
>>> b
array([ 1., 2., 2., 2., 4., 4.])
>>> c = np.around(a).astype(int) 🗻
>>> C
array([1, 2, 2, 2, 4, 4])
```

### **Casting:** is the transformation of a variable between different data types

When making operations with different data types, the output will be the bigger data type involved.

#### **Careful with Down - casting**

Example: Floats will be truncated when passing to integers.

You can also force a cast of an array.

You can use the around() to round values.

The result is casted, and you may want to force the cast to a different data-type.

Polynomials

```
>>> #polynomials
   #3x**2 + 2*x - 1:
... p = np.poly1d([3, 2, -1])
>>> p(0)
-1
>>> p.roots
array([-1.
                     0.33333333]
>>> p.order
>>> p.c
array([3, 2, -1])
>>> q = p *
>>> Q
poly1d([ 9, 12, -2, -4,
>>> q.order
```

Polynomials with 1 variable can also be represented by a numpy object (poly1d).

Definition of a polynomial can be done using its coefficients in a list: Example:  $3x^2 + 2x - 1$ :
List:  $[3,2,-1] \rightarrow [a2,a1,a0]$ 

There are some useful methods:

- getting the roots
- getting the order
- getting the coeficients

You can also perform direct operations with polynomials.

Reading and writing data to files with Numpy

```
>>> import numpy as np
>>> data = np.loadtxt('populations.txt')
>>> data
array([[ 1900., 30000.,
                           4000., 48300.],
         1901., 47200.,
                           6100.,
                                   48200.].
         1902.,
                70200.,
                           9800.,
                                   41500.],
         1903..
                 77400.,
                          35200.,
                                   38200.11)
```

Using loadtxt() you can directly obtain the data.

Careful with header in files. They should start/with the spetial caracther '#'

You can also save the data directly to a file with savetxt().

```
populations.txt (~/Dropbox/Python/AdvancedCours
      Open ▼ 🛂 Save 🖺 🤚 Undo 🧀
 populations.txt x
 # vear hare
                lvnx
                       carrot
 1900
        30e3
                4e3
                       48300
        47.2e3 6.1e3 48200
 1901
4 1902

                                                 INS
```

### Good Practices in Python

- Explicit variable names (no need of a comment to explain what is in the variable)
- Style: spaces after commas, around =, etc. A certain number of rules for writing "beautiful" code (and, more importantly, using the same conventions as everybody else!) are given in the Style Guide for Python Code and the Docstring Conventions page (to manage help strings).
- Except some rare cases, variable names and comments in English.
- Good identation (forced in Python)
